## Multi Stage Growth

## Capital Budgeting

- Calculating Cash Flows
- Capital Rationing

## Price to Earnings Ratio (P/E)

A P/E ratio ("share price" over "earnings per share") is often viewed as an indicator of how "good" a firm is.

Using the Gordon Growth Model,

$$
\frac{P_{0}}{\operatorname{EPS}_{1}}=\frac{1-b}{r-g}
$$

- P/E ratios are primarily affected by the growth rate
- Compare firms in the same risk class and plowback ratio, i.e. "r" and "b" are more or less the same. Then, a high "g" means a high P/E ratio.

Lets look at some examples: EBAY, DELL and General Motors

| Last Trade: | 81.734 | Day's Range: | 79.90-81.98 | EBAY' 26-Apr @ 11:26am (C)Yahoo! |

GM's P/E ratio 11.13

We will use the Gordon Growth Model to evaluate stocks of firms with time changing growth rates.

## Multi Stage Growth

Example: Find the value of a firm for which:

- From year 1 through $12, \mathrm{ROE}=12 \%$,and $\mathrm{b}=100 \%$ (high growth stage)
- From year 13 on, ROE $=10 \%$ and $b=40 \%$
$-\mathrm{BE}_{0}=\$ 50$ and $\mathrm{r}=10 \%$

The growth rate for the first 12 years is ROE x b = 12\%
$\mathrm{BE}_{12}$ is $\$ 50(1+\mathrm{g})^{12}=\$ 194.8$.

The dividend at time 13 is $\operatorname{DIV}_{13}=\mathrm{BE}_{12}(10 \%)(1-0.4)=\$ 11.68$.

The new growth rate is $\operatorname{ROE}_{\text {new }} \times b_{\text {new }}=10 \%(0.4)=4.0 \%$

Using GGM the stock price at time 12 is $\mathrm{P}_{12}=\operatorname{DIV}_{13} /(\mathrm{r}-\mathrm{g})=\$ 194.8$

## Multi Stage Growth

The share price is the discounted value of dividends .

There are no dividend payments for the first 12 years. The first dividend payment is due at time 13.

So ... the current stock price is the discounted future stock price at time 12,

$$
\begin{aligned}
P_{0}= & \frac{1}{(1+r)^{12}} \times P_{12}+P V(\text { div's for first } 12 \text { years }) \\
& \Rightarrow P_{0}=\frac{1}{(1.10)^{12}} \times 194.8=\$ 62.07
\end{aligned}
$$

## Capital Budgeting:

## Net Present Value (NPV)

## Capital Budgeting: Net Present Value (NPV)

Corporations will choose a project only if the PV of outflows is smaller than the PV of inflows, i.e. if the NPV is positive.

The NPV of a project is: $N P V=C_{0}+\frac{C_{1}}{(1+r)^{1}}+\ldots+\frac{C_{n}}{(1+r)^{n}}$
Where "Net" refers to the fact that $\mathrm{C}_{0}$ (for example) may be negative (outflow) and represent the investment in the project.

Decision rule:
(1) In the case of a single project (or many independent projects): accept the project if and only if NPV>0.
(2) In the case of mutually exclusive projects, accept the project with the highest NPV, if that NPV>0.

## Calculating Cash Flows

To get a valid NPV we discount the actual, after-corporate-tax, incremental cash flows, that we get from taking on a project.

Rule 1: Use actual cash flow attributed to the project

- Use incremental cash flows
- Forget sunk costs
- Include opportunity cost of using existing equipment, facilities, etc. as outflows.
Rule 2: Be consistent in the treatment of taxes.
- Discount after-tax cash flows with the after-tax interest rate.

Rule 3: Use actual cash flows - not accounting earnings.

## Calculating Project Cash Flows

$\mathbf{C}_{\mathbf{t}}=(\text { Project Cash Inflows })_{\mathrm{t}}-(\text { Project Cash Outflows })_{\mathrm{t}}$
$=(\text { Project Operating Revenues })_{t}$

- (Project Operating Expenses Except Depreciation $)_{t}$
- (Project Capital Expenditures $)_{t}-(\text { Project Income Taxes })_{t}$
- We don't include accounting depreciation as an expense because it is not a real expense.
- However, depreciation does affect cash flows because it reduces tax payments.
$(\text { Project Income Taxes })_{t}=(\text { Tax Rate })_{t} \times(\text { Project Revenues })_{t}$
- (Tax Rate $)_{t} \times(\text { Project Expenses Except Depreciation })_{t}$
- (Tax Rate $)_{\mathrm{t}} \mathrm{x}$ (Depreciation) ${ }_{\mathrm{t}}$

## Calculating Project Cash Flows

## key equation for project cash flows

Taxable earnings $=$ Project Operating Revenues - Operating Expenses - Depreciation
$\mathbf{C}_{\mathbf{t}} \quad=$ Project Operating Revenues - Operating Expenses

- t( Taxable earnings) - Capital Expenditures
- Operating Expenses above are "Operating Expenses Except Depreciation" i.e. do not include Depreciation
- " t " is the corporation's marginal tax rate

Example: You have just purchased a machine for $\$ 1 \mathrm{M}$ with a life of 10 years. Each year it produces revenues of $\$ 300,000$, and operating expenses of $\$ 100,000$. Assume that the machine will be depreciated over 10 years using straight-line depreciation, and have no salvage value. The Corporate tax rate is $40 \%$. What are your annual after-tax cash flows?

Depreciation schedule
\$100K \$100K

Time: $0 \quad 1$
2

## Calculating Cash Flows:

Date 0: revenues are $\$ 0$, expenses are $\$ 0$, capital expenditures are $\$ 1 \mathrm{M}$ and depreciation is $\$ 0$

> Taxable earnings $=\$ 0-\$ 0$
> Cash flow $=\$ 0-\$ 0-0.4(\$ 0)-\$ 1 \mathrm{M}=-\$ 1 \mathrm{M}$

Date 1-10: revenues are $\$ 300 \mathrm{~K}$, operating expenses are $\$ 100 \mathrm{~K}$, capital expenditures are $\$ 0$ and depreciation is $\$ 100 \mathrm{~K}$

Taxable earnings $=\$ 300 \mathrm{~K}-\$ 100 \mathrm{~K}-\$ 100 \mathrm{~K}=\$ 100 \mathrm{~K}$

Cash flow $=\$ 300 \mathrm{~K}-\$ 100 \mathrm{~K}-0.4(\$ 100 \mathrm{~K})=\$ 160 \mathrm{~K}$

## Working Capital

There are typically timing differences between the accounting measure "Sales - Cost of Goods Sold" and cash flows. This difference is "Working Capital",

Working Capital $=$ Inventories + Accounts Receivable - Accounts Payable

- Inventory: An increase in inventory is a real cost - even if these goods are not sold in the current year.
- Accounts Receivable: If we haven't received payments we shouldn't count it as a cash flow.
- Accounts Payable: If we haven't paid suppliers yet we shouldn’t count it as a cash flow.

> Change in Working Capital should be treated as an expense

Example 1: You run a chain of stores that sells sweaters. At time 0 you buy 1 M sweaters at a price of $\$ 30$ each. At time 1 you sell 500K sweaters for $\$ 60$ each and at time 2 you sell 500 K sweaters for $\$ 60$ each. The corporate tax rate is $40 \%$. What are your after tax cash flows?

| T | After tax <br> [Sales - Cost of Goods Sold] | Inventory | Change in <br> Working Capital | Cash flow |
| :---: | :---: | :---: | :---: | :---: |
| 0 | $\$ 0$ | $\$ 30 \mathrm{M}$ | $\$ 30 \mathrm{M}$ | $-\$ 30 \mathrm{M}$ |
| 1 | $0.5 \mathrm{M}(\$ 60-\$ 30)(1-0.4)=$ <br> $\$ 9 \mathrm{M}$ | $\$ 15 \mathrm{M}$ | $-\$ 15$ | $\$ 9 \mathrm{M}+\$ 15 \mathrm{M}=$ <br> $\$ 24 \mathrm{M}$ |
| 2 | $0.5 \mathrm{M}(\$ 60-\$ 30)(1-0.4)=$ <br> $\$ 9 \mathrm{M}$ | $\$ 0$ | $-\$ 15$ | $\$ 9 \mathrm{M}+\$ 15 \mathrm{M}=$ <br> $\$ 24 \mathrm{M}$ |

Example 2: The United Sporting Goods Company (USG) is thinking of replacing its eight-year-old machine used to finish aluminum baseball bats. The new machine will put a satin finish on the bats. Should USG undertake the project?

- A marketing study that cost $\$ 200 \mathrm{~K}$ concludes that the new finish will allow USG to sell the bats for $\$ 0.30$ more than the old bats which currently wholesale for $\$ 8.50$. Also sales are predicted to increase by $10 \%$ to 176 K units per year.
- The new machine costs $\$ 280 \mathrm{~K}$ and has operating costs of $\$ 17 \mathrm{~K}$ per year. The annual operating costs of the old machine are $\$ 25 \mathrm{~K}$.
- The material, labor, general and administrative costs will remain at $\$ 7.00$ per bat.
- The machine will require an increase in accounts receivable and inventory net of payables of $\$ 40 \mathrm{~K}$ which will be recovered at the end of the project.

## Example 2 (continued):

- The old machine has been completely depreciated. Its current market value is $\$ 48 \mathrm{~K}$ and it is expected to last another 7 years at which time it will have no salvage value.
- The new machine is expected to last 7 years at which time it will have a salvage value of $\$ 14 \mathrm{~K}$. It will be depreciated for accounting purposes using straight line depreciation assuming no salvage value.
- USG faces corporate tax rate of $34 \%$ and the appropriate discount rate is $16 \%$.

Should the project be executed?

Incremental cash revenue: New machine produces 10\% more bats and increases the sell price by $\$ 0.30$. Thus, the incremental cash flow revenue is $\$ 0.30(160 \mathrm{~K})+(\$ 8.80-\$ 7)(16 \mathrm{~K})=\$ 76.8 \mathrm{~K}$.
Incremental operating expenses: New machine has operating costs of $\$ 17 \mathrm{~K}$ while the old machine has $\$ 25 \mathrm{~K}$. Thus, the incremental operating expenses are - $\$ 8 \mathrm{~K}$.
Annual depreciation new machine: Straight line depreciation, of $\$ 280 \mathrm{~K} / 7=\$ 40 \mathrm{~K}$.

Change in working capital: At time 0 , an increase in WC of $\$ 40 \mathrm{~K}$. At time 7, a decrease in WC of $\$ 40 \mathrm{~K}$.
Capital expenditure: New machine costs $\$ 280$ at time $t=0$. We receive $\$ 14 \mathrm{~K}$ from selling the new machine, at time $\mathrm{t}=7$ (salvage value is $\$ 0$ ). We get $\$ 48 \mathrm{~K}$ from selling the old machine (fully depreciated).
After tax interest rate: $16 \%(1-0.34)=10.56 \%$

|  | $\mathbf{0}$ | $\mathbf{1 - 6}$ | $\mathbf{7}$ |
| :--- | :---: | :---: | :---: |
| Incremental cash <br> revenue | $\$ 0$ | $\$ 76.8 \mathrm{~K}$ | $\$ 76.8 \mathrm{~K}$ |
| Incremental <br> operating expenses | $\$ 0$ | $-\$ 8 \mathrm{~K}$ | $-\$ 8 \mathrm{~K}$ |
| Capital expenditures | 280 K |  | $\$ 40 \mathrm{~K}$ |
| Depreciation |  |  | $\$ 40 \mathrm{~K}$ |
| Other income | $\$ 48 \mathrm{~K}$ | $\$ 48 \mathrm{~K}$ | $\$ 84.8-\$ 40=\$ 44.8 \mathrm{~K}$ |
| Taxable earnings | $\$ 16.32 \mathrm{~K}$ | $\$ 44.8 \mathrm{~K}(0.34)=\$ 15.2 \mathrm{~K}$ | $\$ 58.8 \mathrm{~K}(0.34)=\$ 20 \mathrm{~K}$ |
| Taxes | $+\$ 40 \mathrm{~K}$ | $\$ 69.87 \mathrm{~K}$ | $-\$ 40 \mathrm{~K}$ |
| Change in WC | $-\$ 288 \mathrm{~K}$ | $\$ 118.8 \mathrm{~K}$ |  |
| After tax operating <br> cash flow |  |  |  |

$$
\mathrm{NPV}=-288+\frac{69.57}{0.1056}\left(1-\frac{1}{1.1056^{6}}\right)+\frac{118.8}{1.1056^{7}}=\$ 68.97 \mathrm{~K}
$$

## Capital Rationing

In general we would like to think that funds will be made available for any positive NPV>0 project, but in practice this is not the case,

- It is difficult to raise additional external funds
- Banks impose limits on firms' credit lines

Example: You are a manager with $\$ 1 \mathrm{M}$ to invest and you have the following possible independent projects:

| Project | Cost | PV inflows | Profitability index | NPV |
| :---: | :---: | :---: | :---: | :---: |
| A | $\$ 200,000$ | $\$ 300,000$ |  | $\$ 100,000$ |
| B | $\$ 500,000$ | $\$ 620,000$ |  | $\$ 120,000$ |
| C | $\$ 400,000$ | $\$ 700,000$ |  | $\$ 300,000$ |
| D | $\$ 200,000$ | $\$ 275,000$ |  | $\$ 75,000$ |
| E | $\$ 100,000$ | $\$ 130,000$ |  | $\$ 30,000$ |
| F | $\$ 100,000$ | $\$ 140,000$ |  | $\$ 40,000$ |

## Capital Rationing

To answer this question we calculate the Profitability Index (PI):

$$
\mathrm{PI}=\frac{\mathrm{PV}(\text { future cash flows })}{\text { Initial Investment }}
$$

Decision rule:
(1) In the case of independent projects accept all projects with PI>1 (this is the same as accepting all projects with NPV>0)
(2) In the case of mutually exclusive projects, among projects with PI>1, start by choosing the one with the highest PI.

## Example (continued):

| Project | Cost | PV inflows | Profitability index | NPV |
| :---: | :---: | :---: | :---: | :---: |
| A | $\$ 200,000$ | $\$ 300,000$ | 1.50 | $\$ 100,000$ |
| B | $\$ 500,000$ | $\$ 620,000$ | 1.24 | $\$ 120,000$ |
| C | $\$ 400,000$ | $\$ 700,000$ | 1.75 | $\$ 300,000$ |
| D | $\$ 200,000$ | $\$ 275,000$ | 1.38 | $\$ 75,000$ |
| E | $\$ 100,000$ | $\$ 130,000$ | 1.30 | $\$ 30,000$ |
| F | $\$ 100,000$ | $\$ 140,000$ | 1.40 | $\$ 40,000$ |

First rank the projects: $\mathrm{C}>\mathrm{A}>\mathrm{F}>\mathrm{D}>\mathrm{E}>\mathrm{B}$.

C
C+A
$\mathrm{C}+\mathrm{A}+\mathrm{F}$
$C+A+F+D$
$\mathrm{C}+\mathrm{A}+\mathrm{F}+\mathrm{D}+\mathrm{E}$ \$400,000

$$
\$ 400,000+\$ 200,000=\$ 600,000
$$

$$
\$ 600,000+\$ 100,000=\$ 700,000
$$

$$
\$ 700,000+\$ 200,000=\$ 900,000
$$

$$
\$ 900,000+\$ 100,000=\$ 1 \mathrm{M}
$$

You don't have enough funds to finance project $B$.
